

Conformity and Soft Skills as Determinants of Alternatively Credentialed Non-College Graduate Hireability

John Vandivier^a

^a4400 University Dr, Fairfax, VA 22030

Abstract

Despite targeting technical skills, vocational school graduates earn less than college graduates. This paper hypothesizes that conformity selection and a perceived deficit in soft skills substantially explain reduced alternatively credentialed non-college graduate (ACNG) hireability. Microdata from the United States confirm a perceived soft skill deficit for ACNG labor. Results indicate that conformity is a critical factor of hireability, but the direction of effect is heterogeneous by employer type. Conformity and perceived skill gaps explain about one-third of hireability variance. Perceived soft skill explains more hireability variance than widely recognized factors like the industry of occupation. Opposite conventional explanation, results suggest that conformity reduces hireability on average. Respondents tend to perceive ACNG candidates as an even mix of high and low performers. Evidence favors employer risk aversion toward labor productivity as a preferred explanation of low ACNG demand. ACNG labor is perceived as low in conscientiousness and body language communication skills compared to college graduates. The conclusion incorporates discussion of public misperception on vocational school costs and suggests activities to reduce unconscious bias.

Keywords: education economics, signaling, alternative education, conformity, vocational

1. Introduction

A substantial gap exists between the skills expected by employers and those possessed by college graduates[1, 2, 3, 4]. Experts view college alternatives, including vocational school, to be useful for technical training, but the traditional college degree retains a wage premium over vocational education. Unemployment, underemployment, and other adverse labor outcomes follow a similar pattern[5]. This paper seeks to resolve the apparent discrepancy between these outcomes while preserving the mainline economic view that employers pay for perceived job candidate skill. To explain the apparent discrepancy, this paper tests the hypothesis that employers expect an offsetting non-technical skill deficit when considering an alternatively credentialed non-college graduate (ACNG). I find evidence that employers and the general population in the United States expect a low level of soft skills from ACNG job candidates.

Alternative credentials refer to credentials other than the undergraduate degree[6]. The category includes, for example, industry certifications, portfolios of work, digital badges, and other records of unaccredited learning and achievement. Individuals pursuing alternative credentials typically intend to leverage it toward better employment. That is, they typically have the same goals as a college student. Many individuals obtain alternative credentials as a supplement to the college degree. Such a situation is Pareto-superior to degree attainment alone and is therefore intentionally excluded from the analysis. This paper focuses on the comparatively interesting case of alternative credentials as a substitute for the college degree to diagnose comparative disadvantage at the skill level. If a specific skill set explains labor outcome differences, alternative learning providers can improve their products to reduce the outcome gap.

The signaling model has become one of the two standard explanations of the value of the college degree. Signaling theory provides three advantages over human capital theory for the present study. First, signaling theory can explain labor outcome variance when human capital is held constant.

Second, the signaling model empowers a questionnaire research design. In an

idealized human capital model, the measures of human capital would correspond to production process inputs. To establish a wide array of such skill measures would be complicated and prone to measurement sensitivities, assumptions, and errors of various kinds. In this framework, a questionnaire is a second-
35 best design that provides a proxy for the functional measure of skill. Signaling theory takes the reverse approach. According to the signaling model, employer perception and evaluation drive their willingness to pay for a job candidate. The manner in which employer perception relates to job candidate technical skill, if at all, is secondary. In this framework, a questionnaire is ideal. An additional
40 benefit of using a questionnaire is the ability to ask hypothetical questions. In pondering hypotheticals, employer evaluation of a credential or signal can be isolated from the human capital variance, which occurs in actual job candidates.

Third, signaling theorists have laid out a testable hypothesis for weak labor outcomes among non-college graduates. Following this model, scholars claim
45 that the college degree signals intelligence, conscientiousness, and conformity[7]. Nontraditional education, in contrast, is hypothesized to signal nonconformity. Nontraditional courses can be completed in a shorter time and with reduced entry qualifications relative to the traditional degree. For this reason, alternative credentials hypothetically signal low conscientiousness relative to the college
50 degree.

Research indicates that employer demand for employee conscientiousness and conformity follows a bliss point pattern. Excess individual conscientiousness can disturb team performance[8]. Conformity can lead to a lack of innovation and suboptimal organizational practices[9]. Conformity selection occurs in part
55 through heuristic rather than deliberate cognition.

Risk aversion is a distinct explanation for conformity selection. Some employers are not able to evaluate an alternative credential with confidence. Such an employer views ACNG labor as a gamble with some odds of positive or negative outlier value. The employer may not prefer to hire such a candidate due to
60 risk aversion, even if their point estimate for ACNG labor value is higher than their point estimate for a recent college graduate. If firm size effects are posi-

tively associated with ACNG hireability, this will add weight to an explanation based on risk aversion.

2. Data and Methodology

65 A simple model of demand for labor provides context for the hypothesis of interest. This model is clarified in Equations 1a and 1b:

$$S_j = f(H_j) \tag{1a}$$

$$w_{ij} = E_i(MRP_j) = f_i(S_j) \tag{1b}$$

Job candidate j , generates a signal of productivity, S_j from unobserved human capital, H_j . Employer i , forms an expectation of the marginal revenue product of j on the basis of $f_i(S_j)$, an employer-specific evaluation of S_j .
70 A specific employer is willing to pay a specific job candidate wages of w_{ij} .

This study uses ordinary least squares (OLS) regression analysis to estimate the effect of perceived skill gaps on hireability. An employer is willing to pay more for a relatively hireable individual. The representation of willingness to pay
75 makes hireability a proxy of demand for labor and w_{ij} . This paper hypothesizes that employers preferentially value soft skills in the course of $f_i(S_j)$ to explain the reduced willingness to pay for ACNG labor relative to college graduate labor. If employers do bias toward soft skills in job candidate evaluation, one or more soft skills should yield a negative coefficient in a regression on hireability.

80 This study uses original cross-sectional data from an online self-completed questionnaire ($n = 212$). The data is available for replication or any other use¹. The Amazon Mechanical Turk crowdsourcing service provided respondents for the questionnaire. Respondents were United States citizens at or over the age of

¹See https://osf.io/8qtxf/?view_only=95b0c0b0c65e4b7983198cc87c2ab733 for data and statistical analysis code used in this study.

eighteen, paid for participation, and selected on an opt-in, first-come, first-serve
85 basis. The survey administration took place in July of 2020.

The survey includes 65 questions in two sections². The first section captures
respondent characteristics, and the second section captures perceived skill rel-
ative to hypothetical job applicants. Employer responses did not significantly
differ from the general population, so results generally hold for both employers
90 and the United States population.

Regression variables in this study are categorical or Likert-type responses
based on a scale from 1 to 10³. Higher Likert-type values indicate greater
agreement with a statement that varies by variable. Categorical variables in-
clude state of residence, the industry of occupation, employer status, firm size,
95 and a measure called duration.

Duration measures the length of time the respondent believes it takes to
obtain an alternative credential. Employer status describes whether an individ-
ual makes hiring and firing decisions in the course of their employment. The
variable takes one of three values: yes, no, or unemployed. Employer effects
100 refer to the case where an individual states that they do make hiring and firing
decisions. State of residence refers to a state within the United States or the
District of Columbia. While it was permitted, no actual responses identified the
District of Columbia as a residence.

Regression analysis includes three other factor groups, and they are mea-
105 sured using Likert-type units. They include hireability, rulebreaker effects, and
perceived skill gaps. Hireability is the dependent factor. It indicates the degree
of agreement that, "For many professions, alternative credentials can qualify a

²See Appendix A for a full copy of the survey.

³It is an accepted practice to treat Likert-type responses as either categorical or continuous
for regression analysis. Jaccard and Wan provide support for continuous analysis of Likert-
type data. They note that severe departures from the assumptions on cardinality "do not
seem to affect Type I and Type II errors dramatically," particularly when the Likert scale is
five or more points[10]. This paper uses a 10-point scale and treats these data as continuous.
A 10-point scale is equivalent to a continuous response from 1 to 10 with rounding.

person for an entry-level position.”

Rulebreaker effects refer to a collection of three factors that measure respondent agreement with statements about nonconformists, or “People who are willing to break formal or informal rules and norms.” The first statement indicates that nonconformists present a risk to a company’s reputation, productivity, or value. This statement received the least agreement and greatest response variance among three qualitatively different descriptions of nonconformists ($\mu = 6.40, \sigma = 2.55$).

The second statement indicates that nonconformists are held back by rules and “could just as easily be high performers as low performers.” This statement received the most agreement and least variance among rulebreaker statements ($\mu = 7.42, \sigma = 1.91$). The agreement with this statement provides evidence against the thesis that employers value conformity for its own sake. In turn, this adds weight to the theory that employers value conformity as a risk aversion tactic while knowing that nonconformity signals positive outlier potential. The third description of nonconformists states that they are creative, innovative, and may benefit company culture ($\mu = 7.25, \sigma = 2.03$).

Perceived skill questions in the second section of the survey allow for two ways to calculate perceived skill gaps. Perceived skill gaps are measured separately with and without overqualification effects. Overqualification effects are important in external research[11, 12], but skill gap analysis that ignores these effects is also routine[13].

Perceived skill is a Likert-type response reporting agreement with the statement that a particular candidate has a particular skill. For each of 13 skills, the respondent imagines and reports skill levels for the ideal candidate, the average actual employee, the average recent college graduate, and the average ACNG. Raw perceived ACNG skill gaps equal the difference of the perceived skill of an ideal candidate with the perceived skill of an ACNG. The perceived skill gap with overqualification effects equals the raw perceived skill gap. The perceived skill gap without overqualification effects is calculated as the raw skill gap or zero if the raw skill gap value is negative.

Rulebreaker effects and perceived skill gaps are structurally linked. One of
140 the skills that respondents evaluate is nonconformity, or "willingness to break
formal or informal rules and norms." Nonconformity interacts with employer
disposition to rulebreaking. For this reason, discussions on the importance of
skill gaps include discussion on rulebreaker effects.

These methods allow for the identification of a preferred model that explains
145 hireability using perceived ACNG skill gaps. The identified model will support
the hypothesis if soft skills are more important than technical skill gaps. The
model will support the risk aversion explanation of ACNG hireability over an
explanation from conformity selection if large employer size is positively associ-
ated with hireability.

150 The last section of results goes over comparative results between ACNG
skill gaps and gaps among recent college graduates. The comparative analysis
provides additional confidence in the data by replicating the hireability gap be-
tween ACNG labor and recent college graduates reported in external research.
Model 6, the initial comparative model, results from an adjustment of Model 5,
155 the preferred noncomparative model of hireability. Each perceived skill gap in
Model 5 is replaced with a comparative skill gap variable to generate Model 6.
Comparative skill gaps equal the perceived skill gap for the ACNG minus the
recent college graduate's perceived skill gap. Multiple regression of these com-
parison factors on hireability demonstrates which, if any, perceived skill gaps
160 are important distinguishers of the ACNG from the college graduate. Identi-
fication of significant differences with a total negative effect on hireability will
replicate external data on the lower job market value of ACNG labor and pro-
vide a diagnostic that can be used by alternative learning providers to assist in
remediating the gap in labor outcomes.

165 3. Results

3.1. Identification of the Preferred Model

Results confirm that employers and the general population associate a soft skill deficit with ACNG candidates. Employer status was associated with an insignificant positive coefficient on hireability. Hireability was generally positive
170 ($\mu = 7.57, \sigma = 1.80$) and depends critically on rulebreaker effects. Rulebreaker effects have more explanatory power than perceived skill gaps, and perceived skill gaps have more explanatory power than widely recognized factors like state of residence and industry. Duration effects, positive nonconformity selection, and the lack of important differences in conformity between ACNG and college
175 graduate labor provide support for an explanation of ACNG hireability based on risk aversion rather than positive conformity selection.

Table 1 reports statistics for five multiple regressions. The table displays selected coefficients for brevity. Selected variables include rulebreaker effects and any perceived skill gap that is important in any specification. In these models,
180 an important factor is one that improves the adjusted explanatory power of the model when included. These factors are not constrained to have a p-value of less than 0.1, but as a rule of thumb, they generally have a p-value of less than 0.3. Of the thirteen perceived skill gaps tested, eight were important in at least one specification. Seven skill gaps were important in Model 5, the preferred
185 model. Evidence is found for an important interaction between the information technology industry and perceived body language communication skills.

Model 1 allows for overqualification. Model 2 uses the perceived skill gap measures that exclude overqualification effects. Models 3 and 4 are equivalent to models 1 and 2, respectively, after normalizing for industry, state, and firm size
190 effects. Effect normalization involves retaining those factors which are robust across both models 1 and 2. For example, Alabama has a significant effect when overqualification is allowed in Model 1. The effect for respondent residence in Alabama is insignificant Model 2, which excludes overqualification. Because Alabama is sensitive to this specification change, it is considered nonrobust and

195 excluded after normalization. Employer status was positive in all models, but
it was only significant in models 1 and 2. Significance loss on employer status
during normalization suggests that the effect of employer status on hireability
critically interacts with the industry, state of residence, and firm size effects,
which are the normalized effects.

200 Making two adjustments to Model 4 yields Model 5. Model 5 drops the
factor for salary. The salary factor improved adjusted explanatory power in
Model 2, but it did not provide that benefit in other models. Moreover, the
p-value of this factor was unacceptably low in Model 4 ($p > 0.9$). The second
adjustment is to insert a variable for duration⁴. The belief that it takes more
205 than a year to obtain an alternative credential is positively correlated with
hireability ($\beta = 0.875, p < 0.01$).

The preferred model explains roughly one-third of the variance in hireabil-
ity. Rulebreaker effects are significant invariant to specification. Six of the
seven perceived skill gaps in the preferred model are measures of soft skill. The
210 perceived technical skill gap coefficient is insignificant, but it does possess an
intuitive negative sign that is robust to specification. The dominant effect of
soft skills in the preferred regression supports the main hypothesis.

In the classic signaling explanation of low ACNG demand, the ACNG signals
an abnormal lack of conscientiousness and conformity. Regression analysis raises
215 three problems for the conformity component of the classic explanation. These
problems are robust to the specification and operationalization of conformity.
First, rulebreaker effects are positively related to hireability. Secondly, a gap
in perceived nonconformity yields a negative coefficient on hireability. This gap
effect is equivalent to an association of low hireability and high conformity.

220 Overqualification is ignored in Model 5, so a positive gap indicates that

⁴Duration is a categorical variable that was important in both Models 1 and 2. As a
categorical variable, it decomposes into a boolean series for factor analysis. Models 1 and 2
retained one or more duration boolean factors, but none overlapped. As a result, models 3
and 4 drop the duration variable.

the job candidate has less skill than an ideal candidate. In this model, an increase in gap size is a reduction in the perceived level of skill possessed by a job candidate. Therefore, the negative coefficient for the nonconformity gap factor indicates that a low level of nonconformity is associated with reduced hireability. Similarly, a high level of perceived nonconformity has a positive effect on hireability. A summary statistic reinforces the point that conformity is not generally in demand: The average actual employee has more perceived nonconformity than either the ACNG or the recent college graduate.

The third reason that an ACNG nonconformity signal does not explain reduced hireability is that ACNG and recent college graduate labor does not significantly differ in perceived levels of conformity. Here, summary statistics demonstrate this. Later, Table 3 reiterates the point from another perspective. That table presents models in which comparative skill gaps between ACNG and recent college graduate labor explain ACNG hireability, but conformity is not an important factor in any such model.

The average level of perceived nonconformity for the ACNG is 6.43, with a standard deviation of 2.25. The average for a recent college graduate is 6.29, with a standard deviation of 2.36. Informally, a lack of significant difference is apparent in that the means differ by less than one-quarter of a standard deviation. Formally, the F-statistic from an analysis of variance ($F = 19.25$) and Pearson's chi-squared test ($\chi = 298.80$) each indicate a probability of independence which is less than 0.0001.

The coefficient on conscientiousness is significant and positive across specifications. Intuition would dictate that a large gap in conscientiousness would be associated with reduced hireability. Regression of the perceived gap in conscientiousness alone on hireability does produce the expected negative coefficient. Attenuation between the direct measure of conscientiousness and its cross-correlates explains the sign change. Conscientiousness is cross-correlated with several factors in each model from Table 1. It could be the case that these cross-correlated effects have partialled from negative variation in conscientiousness. Removing factors for skill gaps and rulebreaker effects from

Model 5 tests this hypothesis. Model 5 retains the other factors for state, industry, duration, and employer status. When specified as such, the factor for the perceived conscientiousness skill gap yields the expected negative coefficient
255 $(\beta = -0.084, p < 0.31)$.

Employer size is an important factor in the preferred model. The largest categorical value for employer size is positively associated with hireability. This value represents employers with 10,000 or more employees. This finding supports the explanation of hireability from risk aversion over positive conformity
260 selection.

Some state and industry effects are important in the preferred model. Regarding industry effects, an interesting interaction between body language communication skills and employment in the information technology industry yields a significant and positive coefficient on hireability. Body language skill gaps are
265 independently associated with reduced hireability. The interaction indicates a reduced penalty for lack of body language communication skills in the information technology industry.

A reduced penalty for soft skill deficit helps explain the particular flourishing of alternative credentials in the information technology industry. The
270 reduced penalty in this particular industry might be related to its relative lack of regulation. Another hypothetical explanation is that the reduced penalty is related to cultural norms in the industry. Suppose that there is a diminished technical need for social skills in programming. In that case, introverts obtain a comparative advantage in this field. Further study that includes personality
275 data is encouraged to test this hypothesis.

3.2. Explanatory Share of Perceived Gaps

The preferred model explains about one-third of hireability variance, but how much of the explanatory power is attributable to perceived skill gaps? Table 2 provides evidence on the importance of perceived skill gaps and rulebreaker
280 effects relative to other factor groups. Industry and state effects are factor groups regarded in external literature as important for models in the labor

Table 2: Factor Group Explanatory Power in a Simple Regression

Effect Group Name	Adj R-Sqr	R-Sqr	Max p-value
Industry	0.0185	0.0510	0.288
Rulebreaker	0.1432	0.1554	0.053
Skill Gaps with Overqualification	0.0558	0.0737	0.106
Skill Gaps without Overqualification	0.0758	0.0933	0.115
State, Robust	0.0177	0.0503	0.227
State, Semi-Robust	0.0034	0.0648	0.831

market. Table 2 shows that perceived skill gaps and rulebreaker effects explain more variance in hireability than do the widely utilized variables for industry and state. Rulebreaker effects collectively explain more than three times as
285 much response variance as do industrial or state effects.

Comparing simple regressions of perceived skill gaps on hireability reproduces the finding from multiple regression analysis that overqualification effects reduce explanatory power. Overqualification effects are heterogeneously signed and curved by skill. As a result, nonlinear analysis is likely to improve ex-
290 planatory power. Isolating overqualification effects into distinct factors may also improve model performance. Such an analysis would also require a larger sample to compensate for the loss of degrees of freedom.

Semi-robust state effects are state effects which are significant in any multiple regression described in Table 1. Robust state effects are the significant factors
295 in a simple regression of semi-robust state effects on hireability. Illinois is an example of a state effect that appears in models 1 and 2 from Table 1 but is not significant in a simple regression of semi-robust state effects on hireability.

The r-squared associated with a simple regression of semi-robust state effects is greater than the r-squared associated with robust state effects. Analysis has
300 shown that perceived skill gaps that include overqualification effects are comparatively weak representations of perceived skill gaps for models of hireability. These two measures allow the computation of a conservative lower-bound on the explanatory ratio of perceived skill gaps to state effects. Perceived skill gaps conservatively explain about 14 percent more variance in hireability than do
305 state effects⁵.

With overqualification, perceived skill gaps explain about fifty percent more of the variance in hireability than industry or robust state effects. Without overqualification, the adjusted explanatory power of perceived skill gaps is about three times the adjusted explanatory power of industry or state effects. Rule-
310 breaker effects are about twice as important as perceived skill gaps. These findings collectively provide evidence that perceived skill gaps and rulebreaker effects are factors of high importance for models of hireability.

3.3. Perceived Gaps Compared to the Recent College Graduate

Table 3 provides two models of hireability where comparative skill gaps are
315 independent factors. Replacing perceived skill gap factors in Model 5 with comparative perceived skill gap factors, then dropping other factors, results in Model 6. Eliminating insignificant factors to maximize adjusted explanatory power in Model 6 yields Model 7. In total, Model 6 drops four factors from Model 7. These four factors each had a p-value greater than 0.55. The maximum
320 p-value in Model 7 is less than 0.16. The maximum p-value in Model 7 is less than 0.16.

Models 6 and 7 demonstrate that a few soft skills do constitute a significant difference between groups. The main differentiator between ACNG labor and the recent college graduate is body language communication skill. Respondents
325 perceive ACNG labor to be deficient in this skill relative to recent college grad-

⁵This is computed as $(0.0737/0.0648) - 1 = .1373$ and rounded to 0.14.

p(F)	0.0610	0.0044	0.0125

* $p < .01$, ** $p < .001$

uates. This comparative disadvantage comes at the price of reduced ACNG hireability.

Conscientiousness and willingness to commute are the other two comparative skill gaps in Model 7. These two factors are positively signed, smaller in magnitude, and of lower significance than the factor for body language communication skills.^z Model 7 plus summary statistics on the average value for each independent variable demonstrates that the average total effect of comparative skill gaps on hireability is negative⁶. This total negative effect replicates external research that shows lower demand for ACNG labor.

The average effect of an increased comparative gap in willingness to commute is positive on hireability. The fact that respondents perceive ACNG candidates as more willing to commute than recent college graduates explains the positive coefficient. The reverse is true for body language communication skills. The recent college graduate has a larger level of perceived skill on average for body language communication skills. Because the average case favors the recent college graduate, linear optimization provides an average effect for this comparative gap, which negatively affects hireability.

Conscientiousness has a more complicated result. The college graduate has an advantage on average, but the coefficient remains positive. This positive coefficient seems to indicate that the ACNG maximizes hireability by minimizing conscientiousness. The reason is that Model 7 omits important nonlinear effects. Figure 1 is a scatterplot of residuals from a simple regression of comparative conscientiousness on hireability. The plot indicates a residual trend down and to the right with some heteroscedasticity. Looking along the bottom of the graph shows an m-shape, which is consistent with cubic effects.

Model 8 captures this curvilinear relationship by expanding Model 7 with

⁶The respective mean values for the comparative gaps in perceived body language skill, willingness to commute, and conscientiousness are -0.1415, 0.0943, and 0.0330. The average total effect on hireability attributable to these effects is computed as: $-0.0579 = -0.3395 * 0.1415 - 0.1574 * 0.0943 + 0.1508 * 0.0330$.

Figure 1: Scatterplot of Residual and Fitted Values for Comparative Gap in Conscientiousness

quadratic and cubic factors. The coefficients in this model are not significant, but the directions of effect are as expected. In this model, the average total effect of the comparative conscientiousness gap on hireability is negative⁷. The average
355 total effect for Model 8 as a whole is also negative⁸. When the comparative gap in conscientiousness increases above the average of 0.33, the linear effect is negative and the marginal effect is also negative, but the marginal effect is becoming less negative as conscientiousness increases.

Models 7 and 8 provide a skill-level diagnostic in service of closing the de-
360 mand gap for ACNG labor. Alternative learning providers can implement body language communication training in their products, or ACNG candidates can

⁷Computed as: $-0.0018 = -0.0524 * 0.0330 - 0.0465 * 0.0330^2 + 0.0380 * 0.0330^3$

⁸Computed as: $-0.0293 = -0.1444 * 0.1415 + 0.0340 * 0.1415^2 - 0.0194 * 0.1415^3 - 0.0803 * 0.0943 - 0.0112 * 0.0943^2 - 0.0023 * 0.0943^3 - 0.0524 * 0.0330 - 0.0465 * 0.0330^2 + 0.0380 * 0.0330^3$

obtain additional training and credentials that target this skill a la cart. ACNG
job candidates can offset perceived conscientiousness deficit by provisioning work
history or results of a personality test. External research indicates that psy-
365 chological therapy and other interventions can boost conscientiousness in some
cases[14].

4. Conclusion

This study provides evidence that skill signals are an important factor of
hireability and are unique for the ACNG. Perceived skill gaps do a better job
370 of explaining hireability than other widely recognized effects like industry and
state effects. Employer factors better explain candidate hireability than do
the perceived skill gaps themselves. Technical skill gaps explain less about
hireability than soft skill gaps for ACNG job candidates.

The classic signaling model explanation for employer preference of college
375 graduate labor over ACNG labor is that the college degree provides a compara-
tive signal of conscientiousness and conformity. The present paper finds evidence
that conscientiousness is an important comparative difference contributing to
weak ACNG demand, but conformity does not have such a general effect. This
paper finds that employers of different types have qualitatively different views
380 about conformity. Some employers demand conformity, but many demand non-
conformity.

This paper provides evidence that some employers engage in conformity
selection to avoid risk to the reputation, productivity, or value of a company.
Ironically, such employers fail to conform to normal behavior. Respondents
385 most often preferred to describe nonconformists as individuals who could just as
easily be high performers as low performers. An explanation from risk aversion
is preferred because it explains low ACNG labor demand from an employer
given either of the above responses. Positive conformity selection is only able
to explain the former case.

390 Risk aversion and conformity selection are both partially unconscious biases

that lead to an inefficient organizational operation. A practical recommendation is for organizations to implement bias controls concerning ACNG evaluation. An example control would be to provide human resource procedures for formal evaluation of particular credentials relevant to specified job families. These procedures provide immediate operational benefits regarding known credentials and job families. These procedures should also be retained for ongoing application as new credentials are developed and encountered over time.

Another action item is for educational institutions, policymakers, and the general public to invest further in correcting alternative education misinformation. A survey on trade schooling taken in 2019 provides evidence on the role of this kind of misinformation[15]. Only 27 percent of respondents correctly responded that lower debt is an advantage of enrolling in trade school relative to college. Additionally, over 75 percent of respondents failed to notice that trade school graduates receive industry employment sooner and receive specialized training when compared to a four-year college.

Obtaining a college degree after obtaining some work experience will allow students to leverage employer tuition benefits. Because ACNG hireability varies importantly by the particular employer, ACNG job candidates can reduce the risk of a lengthy job search by applying to many employers at the outset of the job search. Social networking, online research into firm policy, and consulting with recruiters or other industry specialists are tactics to apprehend whether a particular employer is a likely member of the set that is favorable to ACNG labor.

The preferred model explains about one-third of hireability. Perceived skill gaps and rulebreaker effects account for most of the explanatory power in the model. There are several means of extending this research to provide improved explanatory power. A longitudinal study would allow for causal analysis and improve forecasting of ACNG hireability in the future. Other research has conducted some dynamic analysis of the same dependent variable with different regressors[16]. Analysis that includes overqualification effects and heterogeneous nonlinear relations between skill gaps and hireability would improve estimates

of hireability for a candidate of a particular skill profile.

This paper noted that large employers and the information technology industry have a peculiar susceptibility to alternative credentials, so recent changes
425 implemented by Google may indicate future trends. Google has not required a college degree since before 2013[17]. Laszlo Bock, then Senior Vice President of People Operations at Google, stated the following in 2013: "After two or three years, your ability to perform at Google is completely unrelated to how you performed when you were in school, because the skills you required in college are very different." In 2020, Google added three new certificate programs
430 to an existing set and declared that all of its certificates are equivalent to an undergraduate degree for their hiring purposes[18].

If perceived skill represents actual skill, then this study provides evidence that employers should be more willing to hire an ACNG. At the same time,
435 this paper provides evidence that perceived and actual skill levels sometimes do not align. For example, the average recent college graduate in the sample has more perceived technical skills than the average ACNG. The perceived technical deficiency among ACNG labor is surprising because last-mile training, a kind of alternative education, has been specifically recommended in popular literature
440 to remedy the technical skill gaps among recent college graduates. Further study of the differences between perceived and actual skills is encouraged.

Employers seem to be favorable to individuals with alternative credentials. In many cases, employer-perceived skill gaps are not statistically different when comparing recent college graduates with ACNG candidates. Instead of looking
445 to actual or perceived skill differences, the college degree's social status may be better explained by public ignorance about appropriate alternative programs, a lack of appropriate programs for certain occupations, and government policy that gives preference to accredited education.

Conformity and Soft Skills as Determinants of Alternatively Credentialed Non-College Graduate Hireability

Appendix A – Survey Questions

Priming Message for Initial Survey Questions:

This survey asks questions about so-called alternative credentials. For the purposes of this survey, alternative credentials include certificates, documents, and other proof of receiving education, other than traditional credentials. Traditional credentials include a high school diploma or an undergraduate degree from an accredited university. Five specific examples of an alternative credential include a Certified Project Manager certification, a portfolio of work, a Khan Academy profile, or a Nanodegree from Udacity.

There are two sections. The first section of questions is intended to take 5-10 minutes, and the second section is intended to take less than 10 minutes.

Initial Survey Questions:

1. Do you contribute to hiring and firing decisions at your company?
 - a. Select one of the following:
 - i. Yes
 - ii. No
 - iii. Unemployed
2. If you do contribute to hiring and firing decisions, please write the most common job title for which you make such decisions. If you do not, please write your current or most recent job title. If you have never held a job of any kind, write “n/a.”
 - a. Free text response.
 - b. Job title is mapped to average salary using PayScale.
3. Thinking about the job title provided in response to the second question, are you aware of any alternative credentials which would be required, recommended, or applicable for this job?
 - a. Select one of the following:
 - i. Yes. Certification, license, or other non-degree credentials are required by law.
 - ii. Yes. Certification, license, or other non-degree credentials are an industry norm.
 - iii. Yes. Certification, license, or other non-degree credentials are not required or expected, but there are some which are common and valued.

- iv. No. I do not know of any credentials which are common, valued, or legally required in that line of work.
 - v. Not Applicable
- 4. How long do you believe it usually takes to obtain an alternative credential?
 - a. Select one of the following:
 - i. Under a week
 - ii. Under a month
 - iii. Under 3 months
 - iv. Under 6 months
 - v. Under a year
 - vi. More than a year
- 5. Roughly how many full-time employees currently work for your organization?
 - a. Select one of the following:
 - i. 1-10
 - ii. 11-50
 - iii. 51-200
 - iv. 201-500
 - v. 501-1000
 - vi. 1001-5000
 - vii. 5001-10000
 - viii. 10000+
 - ix. I am not currently employed
- 6. For many professions, alternative credentials can qualify a person for an entry-level position.
 - a. Response on a scale from 1 to 10, where a higher score indicates stronger agreement.
- 7. People who are willing to break formal or informal rules and norms probably have a hard time getting along with teams or customers. They present a risk to the reputation, productivity, or value of a company.
 - a. Response on a scale from 1 to 10, where a higher score indicates stronger agreement.
- 8. People who are willing to break formal or informal rules and norms might be doing so because the rules hold them back. They could just as easily be high performers as low performers.
 - a. Response on a scale from 1 to 10, where a higher score indicates stronger agreement.

9. People who are willing to break formal or informal rules and norms tend to be gifted in the areas of creativity and innovation. They are likely to benefit the culture of a company.
- a. Response on a scale from 1 to 10, where a higher score indicates stronger agreement.
10. Which of these industries most closely matches your profession?
- a. Select one of the following and free text when Other is selected:
- i. Agriculture
 - ii. Education
 - iii. Energy
 - iv. Finance, Investment, or Accounting
 - v. Health
 - vi. Information Technology
 - vii. Law
 - viii. Manufacturing
 - ix. Military
 - x. Real Estate
 - xi. Retail
 - xii. Transportation
 - xiii. Other (please specify)
11. Do you work in a STEM profession?
- a. Yes
- b. No
- c. Unsure
12. What state do you reside in?
- a. Select one of the following: The 50 states or the District of Columbia.
13. Gender
- a. Female
- b. Male
- c. Other

Priming Message for Matching Survey Questions:

The next section of this survey is the final section. This section will provide a series of prompts and a response on a scale from 1 to 10 is requested. The response indicates a degree of quality. A response of 1 indicates very little or no quality. A response of 10 indicates a level of quality reserved for the Guinness Book of World Records. There is a total of 52 prompts. The prompts are created by providing 4 variations of 13 basic prompts. Each prompt is meant to be answered within about 10 seconds, so the whole section should take less than 10 minutes.

Matching Survey Questions :

1. The level of physical attractiveness held by an ideal job applicant.
2. The level of physical attractiveness held by a typical employee at my company.
3. The level of physical attractiveness held by a recent college graduate.
4. The level of physical attractiveness held by a non-college graduate with an alternative credential.
5. The level of emotional intelligence held by an ideal job applicant.
6. The level of emotional intelligence held by a typical employee at my company.
7. The level of emotional intelligence held by a recent college graduate.
8. The level of emotional intelligence held by a non-college graduate with an alternative credential.
9. The level of salary required by an ideal job applicant.
10. The level of salary required by a typical employee at my company.
11. The level of salary required by a recent college graduate.
12. The level of salary required by a non-college graduate with an alternative credential.
13. The level of written communication skill held by an ideal job applicant.
14. The level of written communication skill held by a typical employee at my company.
15. The level of written communication skill held by a recent college graduate.
16. The level of written communication skill held by a non-college graduate with an alternative credential.
17. The level of verbal communication skill held by an ideal job applicant.
18. The level of verbal communication skill held by a typical employee at my company.
19. The level of verbal communication skill held by a recent college graduate.
20. The level of verbal communication skill held by a non-college graduate with an alternative credential.
21. The level of body language communication skill held by an ideal job applicant.

22. The level of body language communication skill held by a typical employee at my company.
23. The level of body language communication skill held by a recent college graduate.
24. The level of body language communication skill held by a non-college graduate with an alternative credential.
25. The level of technical job skills held by an ideal job applicant.
26. The level of technical job skills held by a typical employee at my company.
27. The level of technical job skills held by a recent college graduate.
28. The level of technical job skills held by a non-college graduate with an alternative credential.
29. The level of attention to detail, work ethic, timeliness, and organization of work held by an ideal job applicant.
30. The level of attention to detail, work ethic, timeliness, and organization of work held by a typical employee at my company.
31. The level of attention to detail, work ethic, timeliness, and organization of work held by a recent college graduate.
32. The level of attention to detail, work ethic, timeliness, and organization of work held by a non-college graduate with an alternative credential.
33. The level of willingness to break formal or informal rules and norms held by an ideal job applicant.
34. The level of willingness to break formal or informal rules and norms held by a typical employee at my company.
35. The level of willingness to break formal or informal rules and norms held by a recent college graduate.
36. The level of willingness to break formal or informal rules and norms held by a non-college graduate with an alternative credential.
37. The level of customer service skill held by an ideal job applicant.
38. The level of customer service skill held by a typical employee at my company.
39. The level of customer service skill held by a recent college graduate.
40. The level of customer service skill held by a non-college graduate with an alternative credential.
41. The level of teamwork held by an ideal job applicant.
42. The level of teamwork held by a typical employee at my company.
43. The level of teamwork held by a recent college graduate.
44. The level of teamwork held by a non-college graduate with an alternative credential.

45. The willingness to commute or travel to a workplace or even as a part of the daily work, as in commercial trucking, held by an ideal job applicant.
46. The willingness to commute or travel to a workplace or even as a part of the daily work, as in commercial trucking, held by a typical employee at my company.
47. The willingness to commute or travel to a workplace or even as a part of the daily work, as in commercial trucking, held by a recent college graduate.
48. The willingness to commute or travel to a workplace or even as a part of the daily work, as in commercial trucking, held by a non-college graduate with an alternative credential.
49. The willingness to work odd hours or a strange schedule held by an ideal job applicant.
50. The willingness to work odd hours or a strange schedule held by a typical employee at my company.
51. The willingness to work odd hours or a strange schedule held by a recent college graduate.
52. The willingness to work odd hours or a strange schedule held by a non-college graduate with an alternative credential.
