

Dynamic Effects of H-1B and Section 127 Policy Interaction on Higher Education

John Vandivier^a

^a4400 University Dr, Fairfax, VA 22030

Abstract

It is widely believed that employer educational assistance increases the quantity demanded for higher education, but the original passage of Section 127 which enables this tax-deduction for employers is associated with a reduction to the growth of higher education enrollment, and a simple regression of the assistance limit on total enrollment indicates a significant negative correlation. This raises concerns that confounding factors bias estimates of the effectiveness of Section 127 assistance. After taking extensive steps to account for policy effects and other dynamic economic factors, I robustly identify a positive effect on enrollment from employer educational assistance by exploiting real variation in employer educational assistance over the 27-year period from 1990 to 2016. Results are validating using panel vector autoregression (PVAR), dynamic least squares (DOLS) methods, and instrumental variable (IV) approaches. In the preferred model, an increase in tax-deductible employer educational assistance in the amount of one dollar is associated with an increase of about 600 to national total enrollment in institutions of higher education.

1. Introduction

Basic supply and demand theory indicate that a reduction in price is associated with an increase to the quantity demanded. In 1978, a bill was passed allowing employer educational assistance to be tax-deductible in the United States up to a nominal limit of 5,000 dollars. It is surprising, therefore, that 1978 is associated with a local decrease in the growth rate on both total and public university enrollment. This study exploits real variation in the tax-deductible employer educational assistance limit to eventually identify the expected positive effect, but not before identifying and correcting for several interesting things going on in the economy. Specifically, an interaction between H-1B policy and Section 127 employer educational assistance is discovered and assessed.

1.1. Supply-Side Explanations

Before forming more exotic theories, some simpler hypotheses should be checked. One hypothesis is that there is an adjustment period after the passage of Section 127 and before widespread employer provision of the newly deductible benefit. Allowing for a 3 or 5 year lag around the passage of Section 127 in 1978 does not resolve the issue. Across the eight five-year periods from 1970 to 2010, the five-year public enrollment growth rate was above 9 percent as often as it was below. Two of the four low-rate intervals occurred immediately subsequent to the 1978 creation of Section 127. The interval just prior, from 1970-1975, saw the highest growth in enrollment across the period. It does not appear to be a one-year fluke that the employer educational assistance is associated with declined enrollment growth.

Another important point is that Section 127 was passed in 1978, but it took effect in the 1979 tax year. 1979 saw modest growth in enrollment, but given the pre-existing long-run context of positive trend in enrollment, it is not clear that Section 127 can be attributed any causality.

An alternative to the 3 or 5 year lagged analysis is to directly refer to surveys of employers. Cappelli[1] identifies 3 employer surveys from 1992 and 1993

30 which indicate that at least 86 percent of surveyed employers provided educational assistance. These studies were samples of convenience with a focus on large employers, but additional information leads Cappelli to claim that a substantial majority of employers offer such plans over his period of analysis from about 1990 to 2004. Cappelli notes that employee utilization of the benefit favors graduate education with about 20 percent of graduate students receiving
35 employer assistance and roughly 6 percent of undergraduates doing so. Common provision of the benefit has remained true in later years. In 2013, SHRM reported that 61 percent of employers offer tuition assistance[2]. In 2017, World at Work found that 85 percent of employers offered such a benefit, with another
40 7 percent offering non-reimbursement tuition assistance, such as upfront tuition discounts[3].

1.2. H-1B, Veteran Education Benefits, and Stafford Loan Interaction

The idea that graduate students mainly use employer education benefits motivates hypotheses around undergraduate access. Increasingly since the 1990s,
45 developed economies have experienced degree inflation and experience inflation. Entry level positions now require a degree when previously this was not necessary, even when technology has made the work easier. It is possible that undergraduate access to employer benefits are reduced simply because employers increasingly hire individuals that already have the degree. Employers are
50 known to value the degree as a signal of labor quality, but these days there are plenty of other, richer data sources on quality for certain professions. In computer programming we see some employers completely dropping the degree requirement and preferring technical interviews, digital portfolio evaluation, and other signals. Why, then, do other leading employers continue to require the
55 degree? One answer is that the degree requirement forms an H-1B justification. Since the passage of the Immigration Act of 1990[4], a corporation must claim a shortage of qualified specialized labor to justify an H-1B. The "attainment of a bachelor's or higher degree" is written into the law as a test of whether labor is qualified and specialized. This would motivate employers to begin requiring

60 the degree in order to obtain cheap immigrant labor, even while knowing the degree may not be necessary.

Zero employers offered Section 127 educational assistance in 1977, but the majority offered the benefit by 1993. Immigration policy is a change which interrupts this period of analysis, but there are two other major policies to
65 take note of. Stafford loans were available before Section 127, but the limits and rules for these loans and other government assistance to higher education fluctuated over the period of analysis. Government educational benefits for veterans is another major policy in the higher education assistance space. It becomes difficult to imagine a proper Section 127 analysis which does not include
70 dynamic correction for these potentially important factors, as well as correction for general price changes and economic conditions in the economy over time. Such a corrected analysis is exactly what this paper completes.

1.3. Demand-Side Explanations

The prior explanations constitute a supply-side exploration of the importance of Section 127. An alternative explanation is that there simply wasn't
75 much demand for college in the early years of Section 127. Indeed, lack of market demand appears to be a good explanation for the consistent college-age enrollment percent which is observed at 25.7 percent in both 1970 and 1980. A demand-side explanation is consistent with the falling average tuition and fees
80 observed for all institutions from 1972 to 1980. After 1980 we see an upward trend in price and also an upward trend in college-age enrollment percentage, as well as simple total enrollment.

With an increase to the Stafford limit in the 1977 school year, a major change to veteran education benefits in the 1981 school year, Section 127 beginning in
85 the 1978 school year, and price changes in higher education and for all other goods, claims about a particular cause become dubious without full and corrective statistical treatment. Even so, there is some plausibility to the claim that Section 127 was passed during a time when demand was weak, so that there may have been a positive effect on the part of Section 127 as early as the first

90 year, but it was overshadowed by general decline. The main contribution of this line of thought to a more general analysis is that corrective statistics should include price data for education in particular, and also for the general economy.

2. Empirical Model

Equation 1 is an ordinary least squares model of total enrollment higher
95 education in the United States.

$$Y = \beta_1 X_1 + \beta_2 X_2 \dots + \beta_k X_k + e \quad (1)$$

The Section 127 policy effect is the variable of interest. Three other policy variables are included for federal lending policy, veteran education benefits, and H-1 Visa policy. In addition to the four policy variables, enrollment is modelled as a function of time, and the price of tuition and fees. A variable for personal
100 consumption expenditures (PCE) as an measure of inflation is also included.

For robustness and analytical completeness, I test two other left hand variables using ordinary least squares, then I also test the relation of interest with two other modelling approaches. Specifically, I explore vector autoregressive (VAR) models and an instrumental variable regression following the Ander-
105 son-Hsiao pattern[5] with the lagged variable of interest as an instrument.

3. Data

Information on total enrollment for all degree-granting postsecondary institutions in the United States is provided by the National Center for Education Statistics (NCES)[6]. Enrollment figures are for the fall semester of the school
110 year. Information on selected years from 1947 to 2028 is provided, where values for 2018 and later are projected. The present study does not use any of the projected values. Other data sources and policy considerations constrain the period of interest to the 27-year period from 1990 to 2016.

Personal Consumption Expenditures (PCE) data is a measure of inflation
115 provided by the U.S. Bureau of Economic Analysis (BEA)[7]. Education-specific

inflation is also calculated using NCES data[8]. NCES data is the average tuition and required fees for full-time undergraduate students across all degree-granting postsecondary institutions. NCES provides nominal values and values adjusted for the consumer price index (CPI) for tuition. The price of room and board is
120 ignored.

Nominal Section 127 limits are a matter of public law. Section 127 took effect beginning after December 31, 1978 with a nominal assistance limit of 5,000 dollars[9]. In October 1986, Pub. L. 99-514 increased the nominal assistance limit to 5,250 dollars[10]. Real Section 127 employer assistance limits are calcu-
125 lated two ways. One variable is constructed for each measure of inflation. Price deflators for each measure of inflation use 2016 as a base year.

Changes to veteran education benefits are also a matter of public law. A categorical variable is used to capture the state of veteran education benefits among five possible states over the period from 1970 to 2020. The Servicemen's
130 Readjustment Act of 1944, also called the G.I. Bill, is the first interesting case of veteran benefits, but it precedes the period of interest for this study.

The original bill expired in 1956[11]. This expired state is the first state represented by the veteran education state variable. The Veterans Educational Assistance Program (VEAP) was established in 1981[12]. A third period of
135 interest begins in 1984 with the enactment of the Montgomery GI Bill[13]. A fourth period of interest begins in 2009 with the Post-9/11 GI Bill.

Finally, many benefits from the Forever GI Bill became effective in 2018, with additional provisions taking effect in 2020 and 2022[14]. This fifth policy state is too recent to be included in the period of interest. The recent changes
140 in veteran education benefits are a critical caveat for any attempt at forecasting or prediction outside of the period of study.

Due to constraints on the availability of other right hand variable data, the main period of regression analysis ranges from 1990 to 2016. Veteran education benefits exhibit only one change during this period, but this factor proves to be
145 significant in the preferred model.

Stafford loan data is another key component of the analysis. Stafford loan

data is directly relevant by itself, but it is further intended a proxy for broader non-military federal student aid policy. There are two variables for Stafford loans. The first is the nominal loan limit for undergraduates. The second
150 is a dummy variable indicating whether the undergraduate loan limit is the combined limit for undergraduate and graduate loans. A policy change became effective in 1993 which grouped these limits together. Stafford loan data is sourced from FinAid[15].

Visa policy is a complex issue. Annual H-1B visa award is an important
155 and simple variable used for the purposes of this study. The Immigration Act of 1990 decomposed the existing H-1 visa into distinct H-1A and H-1B categories. Over time, H-1B1 and H-1C classifications were established, and many other important but less relevant classifications outside of the H-1 family exist as well. The H-1B visa is most relevant for this study because it specifically
160 relates to the undergraduate degree. The Immigration Act of 1990 makes available the H-1B classification for specialized workers, or workers in a specialty occupation. A specialty occupation is formally defined as "an occupation that requires...attainment of a bachelor's or higher degree..."

H-1 visas are a subgroup of nonimmigrant visas. Nonimmigrant visa award
165 data by classification from 1987 to 2019 is provided by the Bureau of Consular Affairs within the United States State Department[16]. This paper exclusively uses the most relevant H-1B visa award numbers, but reanalysis with other visa classifications could yield statistically significant findings. The prior H-1 visa was also a merit worker visa, but it had no formal definition of merit. In
170 1989, 48,820 H-1 visas were awarded. In 1991, 7,443 H-1A visas were awarded, and 51,882 H-1B visas were awarded. It's plausible that the college-educated effect informally existed prior to the 1990 legislation. One might also find small but significant effects by looking into visas outside the H-1 family. Besides the number of actual visa awards, an analyst could look for visa cap effects, or visa
175 policy state effects. For example, Pew Research Center notes that the American Competitiveness in the 21st Century Act of 2000 exempts certain entities from the H-1B cap[17].

The last data source of interest is on actual federal loans. Actual federal loans stand in contrast to loan limits which are represented by the Stafford loan limit variable. Loan limits are a policy choice, but after correcting for loan limits the actuals primarily represent a demand effect. As such, we would not want to correct for actual loans. That would wipe out the effect of interest, which is the demand effect attributable to various policies, and Section 127 employer educational assistance in particular.

Instead, loan data is taken as a left hand variable of secondary interest. Section 127 is taken as a right hand variable in that brief investigation. This allows us to briefly review the relationship between Section 127 employer assistance and the student debt crisis, a potentially related topic of importance. The variable I use in this regard is total federal undergraduate loans, which is extracted from a data set provided by College Board[18]. Given additional context provided by The College Board in a related report[19], it is plausible that a separate analysis which decomposes decomposing aggregate total federal loans by type of loan may yield marginal statistical improvement.

4. Results

The key independent variable is H-1B visa issuance, but at the outset there are two potential left hand variables available. Ordinary least squares (OLS) multiple regression of visa effects, time, and tuition was run against both total enrollment and public university enrollment. Total enrollment was more predictable overall, so this was selected as the preferred enrollment variable.

With total enrollment as the explained variable, a kitchen sink multiple regression was used to select the strongest factors among other factor groups. The total number of visas issued across classification is not significant. The long regression of interest has higher unadjusted explanatory power compared to kitchen sink regression. Measures of tuition were identified as insignificant. Table 1 is a table of regressions which helps illustrate that, somewhat surprisingly, real measures of employer assistance capture price and inflation effects in

a preferred way compared to using a more direct measure of tuition.

H-1 visa effects, on the other hand, are highly significant and complex. All H-1 visa issuance factors are significant with $p < .1$. Somewhat surprisingly, the
210 total number of visas issued within the H-1 family is more significant than the

Section 127 assistance limits which are deflated using education-specific prices were identified as less significant compared to PCE-deflated Section 127 assistance. PCE remained important as a distinct variable.

This makes some sense in the context of a multiple regression. PCE and
215 other factors already represent effects from inflation. While Section 127 assistance deflated for education-specific inflation was identified as insignificant, nominal tuition seems to represent the same education-specific price information.

1. $\Delta .995$ adjusted r^2 for preferred ols model 2. Δ empassist has positive
220 coefficient in the range of 150-850; preferred measure around 600 3. visa effects are complex and important, but signing the effect is sensitive to specification 4. stafford and gi bill effects are also significant in the preferred model.

I also tested PCE as a distinct independent variable. In neither case did PCE present as a significant factor. The second approach turned out to be
225 more significant ¹.
